Reviewing CALL & Intro To Digital Circuits
Example C Program: Hello.c

```c
#include <stdio.h>

int main()
{
    printf("Hello, \%s\n", "world");
    return 0;
}
```
.text
.align 2
.globl main
main:
    addi sp,sp,-16
    sw ra,12(sp)
    lui a0,%hi(string1)
    addi a0,a0,%lo(string1)
    lui a1,%hi(string2)
    addi a1,a1,%lo(string2)
call printf
    lw ra,12(sp)
    addi sp,sp,16
    li a0,0
    ret
.section .rodata
.balign 4
string1:
    .string "Hello, %s!\n"
string2:
    .string "world"

# Directive: enter text section
# Directive: align code to 2^2 bytes
# Directive: declare global symbol main
# label for start of main
# allocate stack frame
# save return address
# compute address of
#   string1
# compute address of
#   string2
# call function printf
# restore return address
# deallocate stack frame
# load return value 0
# return
# Directive: enter read-only data section
# Directive: align data section to 4 bytes
# label for first string
# Directive: null-terminated string
# label for second string
# Directive: null-terminated string
Assembled Hello.s: Linkable Hello.o

00000000 <main>:
0:  ff010113 addi sp,sp,-16

24: 01010113 addi sp,sp,16
28: 00000513 addi a0,a0,0
2c: 00008067 jalr ra
Linked Hello.o: a.out

000101b0 <main>:
  101b0: ff010113 addi sp,sp,-16
  101b4: 00112623 sw ra,12(sp)
  101b8: 00021537 lui a0,0x21
  101bc: a1050513 addi a0,a0,-1520 # 20a10 <string1>
  101c0: 000215b7 lui a1,0x21
  101c4: a1c58593 addi a1,a1,-1508 # 20a1c <string2>
  101c8: 288000ef jal ra,10450    # <printf>
  101cc: 00c12083 lw ra,12(sp)
  101d0: 01010113 addi sp,sp,16
  101d4: 00000513 addi a0,0,0
  101d8: 00008067 jalr ra
Target address of <string1> is \texttt{0x00020 A10}

Instruction sequence \texttt{LUI 0x00020, ADDI 0xA10} does not quite work because immediates in RISC-V are sign extended (and \texttt{0xA10} has a 1 in the high order bit)!

\[
\begin{align*}
0x00020\ 000 + 0xFFFFFFFF\ A10 &= 0x0001F\ A10 \quad \text{(Off by 0x00001 000)}
\end{align*}
\]

So we get the right address if we calculate it as follows:

\[
(0x00020\ 000 + 0x00001\ 000) + 0xFFFFFFFF\ A10 = 0x00020\ A10
\]

What is \texttt{0xFFFFFFFF A10}?

Twos complement of \texttt{0xFFFFFFFF A10} = \texttt{0x00000 5EF} + 1 = \texttt{0x00000 5F0} = 1520_{\text{ten}}

So \texttt{0xFFFFFFFF A10} = -1520_{\text{ten}}

Instruction sequence \texttt{LUI 0x00021, ADDI -1520} calculates \texttt{0x00020 A10}
Static vs. Dynamically Linked Libraries

• What we’ve described is the traditional way: **statically-linked** approach
  • Library is now part of the executable, so if the library updates, we don’t get the fix (have to recompile if we have source)
  • Includes the **entire** library even if not all of it will be used
  • Executable is self-contained
• Alternative is **dynamically linked libraries** (DLL), common on Windows & UNIX platforms
Dynamically Linked Libraries

- Space/time issues
  - + Storing a program requires less disk space
  - + Sending a program requires less time
  - + Executing two programs requires less memory (if they share a library)
  - – At runtime, there’s time overhead to do link
- Upgrades
  - + Replacing one file (libXYZ.so) upgrades every program that uses library “XYZ”
  - – Having the executable isn’t enough anymore

Overall, dynamic linking adds quite a bit of complexity to the compiler, linker, and operating system. However, it provides many benefits that often outweigh these
Dynamically Linked Libraries

• Prevailing approach to dynamic linking uses machine code as the “lowest common denominator”
  • Linker does not use information about how the program or library was compiled (i.e., what compiler or language)
  • Can be described as “linking at the machine code level”
  • This isn’t the only way to do it ...

• Also these days will **randomize layout** (Address Space Layout Randomization)
  • Acts as a defense to make exploiting C memory errors substantially harder, as modern exploitation requires jumping to pieces of existing code (“Return oriented programming”) to counter another defense (marking heap & stack unexecutable, so attacker can’t write code into just anywhere in memory).
In Conclusion…

- Compiler converts a single HLL file into a single assembly language file.
- Assembler removes pseudo-instructions, converts what it can to machine language, and creates a checklist for the linker (relocation table). A `.s` file becomes a `.o` file.
  - Does 2 passes to resolve addresses, handling internal forward references
- Linker combines several `.o` files and resolves absolute addresses.
  - Enables separate compilation, libraries that need not be compiled, and resolves remaining addresses
- Loader loads executable into memory and begins execution.

Clicker Question:
Midterm 1 (In Modern American Written English)

• How was Midterm 1?
  A. 😊
  B. 😐
  C. 😭
  D. 😤
  E. 💩
Hardware Design

- Next several weeks: how a modern processor is built, starting with basic elements as building blocks

- Why study hardware design?
  - Understand capabilities and limitations of HW in general and processors in particular
  - What processors can do fast and what they can’t do fast (avoid slow things if you want your code to run fast!)
  - Background for more in-depth HW courses (EECS 151, CS 152)
  - Hard to know what you’ll need for next 30 years
  - There is only so much you can do with standard processors: you may need to design own custom HW for extra performance
  - Even some commercial processors today have customizable hardware!
Synchronous Digital Systems: Almost Every Processor etc...

- **Synchronous:**
  - All operations coordinated by a central clock
  - “Heartbeat” of the system!
  - *Asynchronous* systems much much much much harder to design & debug

- **Digital:**
  - Represent all values by discrete values
  - Two binary digits: 1 and 0, or True and False
    - Electrical signals are treated as 1’s and 0’s
    - 1 and 0 are complements of each other
  - High/low voltage for true/false, 1/0
  - These days, even a lot of *analog* circuitry is best done as:
    - Put it through an analog to digital converter, do it all digitally in a synchronous circuit, and output to a digital-to-analog converter
Switches: Basic Element of Physical Implementations

- Implementing a simple circuit (arrow shows action if wire changes to “1” or is **asserted**):

  - **On-switch** (if A is “1” or asserted) turns-on light bulb (Z)
  - **Off-switch** (if A is “0” or unasserted) turns-off light bulb (Z)

\[ Z \equiv A \]
Switches (cont’d)

- Compose switches into more complex ones (Boolean functions):

  \[ Z = \text{A and B} \]
  \[ Z = \text{A or B} \]
Historical Note

• Early computer designers built ad hoc circuits from switches
  • Began to notice common patterns in their work: ANDs, ORs, …
• Master’s thesis (by Claude Shannon, 1940) made link between work and 19th Century Mathematician George Boole
  • Called it “Boolean” in his honor
• Could apply math to give theory to hardware design, minimization, …
Transistors

• High voltage ($V_{dd}$) represents 1, or true
  • The Raspberry Pi: $V_{dd}$ ~ 1.2 Volt

• Low voltage (0 Volt or Ground) represents 0, or false

• Pick a midpoint voltage to decide if a 0 or a 1
  • Voltage greater than midpoint = 1
  • Voltage less than midpoint = 0
  • This removes noise as signals propagate – a big advantage of digital systems over analog systems

• If one switch can control another switch, we can build a computer!

• Our switches: CMOS transistors
CMOS Transistor Networks

• Modern digital systems designed in CMOS
  • MOS: Metal-Oxide on Semiconductor
    • Describes how the transistors are constructed
    • These are "Field Effect Transistors" (MOSFETs)
  • C for complementary: use pairs of normally-on and normally-off switches

• CMOS transistors act as voltage-controlled switches
  • Similar, though easier to work with, than electro-mechanical relay switches from earlier era
  • Use energy primarily when switching
    • But not completely: they do "leak" a bit
CMOS Transistors

• Three terminals: source, gate, and drain
• Switch action:
  if voltage on gate terminal is (some amount) higher/lower than source terminal then conducting path established between drain and source terminals (switch is closed)

  ![Diagram showing n-channel and p-channel transistors]

  **n-channel transistor**
  - off when voltage at Gate is low
  - on when:
    - voltage(Gate) > voltage (Threshold)

  **p-channel transistor**
  - on when voltage at Gate is low
  - off when:
    - voltage(Gate) > voltage (Threshold)

Note circle symbol to indicate “NOT” or “complement”

CMOS Circuit Rules

- **Don’t pass** weak values => Use Complementary Pairs
  - N-type transistors pass weak 1’s ($V_{dd} - V_{th}$)
  - N-type transistors pass strong 0’s (ground)
  - Use N-type transistors only to pass 0’s (N for negative)
  - Converse for P-type transistors: Pass weak 0s, strong 1s
    - Pass weak 0’s ($V_{th}$), strong 1’s ($V_{dd}$)
    - Use P-type transistors only to pass 1’s (P for positive)
  - Use pairs of N-type and P-type to get strong values
- **Never** leave a wire undriven (in this class)
  - Make sure there’s always a path to Vdd or GND
- **Never** create a path from Vdd to GND (ground)
  - This would short-circuit the power supply!
CMOS Networks

p-channel transistor
- on when voltage at Gate is low
- off when: voltage(Gate) > voltage (Threshold)

n-channel transistor
- off when voltage at Gate is low
- on when: voltage(Gate) > voltage (Threshold)

Diagram: 
- Inputs: X, Y
- Outputs: Z
- Voltage Levels: 0 Volt, 1 Volt
- Circuit configuration showing voltage states and connections.
Common combinational logic systems have standard symbols called logic gates.

- **Buffer, NOT**
- **AND, NAND**
- **OR, NOR**

Inverting versions (NOT, NAND, NOR) easiest to implement with CMOS transistors (the switches we have available and use most).
Boolean Algebra

- Use plus “+” for OR
  - “logical sum”

- Use product for AND (a\cdot b or implied via ab)
  - “logical product”

- “Hat” to mean complement (NOT)

Thus

\[ ab + a + \overline{c} = a\cdot b + a + \overline{c} = (a \text{ AND } b) \text{ OR } a \text{ OR } (\text{NOT } c) \]
Representations of Combinational Logic (groups of logic gates)

- Truth Table
  - Enumerate Inputs
  - Sum of Products, Product of Sums Methods
  - Use Equivalency between boolean operators and gates
- Boolean Expression
- Gate Diagram
  - Enumerate Inputs
Truth Tables for Combinational Logic

Exhaustive list of the output value generated for each combination of inputs

How many logic functions can be defined with N inputs?
Truth Table Example #1:
y = F(a,b): 1 iff a \neq b

More simplified forms (fewer gates and wires)
And in Conclusion, ...

- Multiple Hardware Representations
  - Analog voltages quantized to represent logic 0 and logic 1
  - Transistor switches form gates: AND, OR, NOT, NAND, NOR
  - Truth table mapped to gates for combinational logic design
  - Boolean algebra for gate minimization
Boolean Algebra: Circuit & Algebraic Simplification

original circuit

\[ y = ((ab) + a) + c \]

\[ = ab + a + c \]

\[ = a(b + 1) + c \]

\[ = a(1) + c \]

\[ = a + c \]

simplified circuit
Laws of Boolean Algebra

\[
\begin{align*}
X \overline{X} &= 0 & X + \overline{X} &= 1 \\
X 0 &= 0 & X + 1 &= 1 \\
X 1 &= X & X + 0 &= X \\
X X &= X & X + X &= X \\
X Y &= Y X & X + Y &= Y + X \\
(X Y) Z &= Z (Y Z) & (X + Y) + Z &= Z + (Y + Z) \\
X (Y + Z) &= X Y + X Z & X + Y Z &= (X + Y) (X + Z) \\
X Y + X &= X & (X + Y) X &= X \\
\overline{X} Y + X &= X + Y & (\overline{X} + Y) X &= X Y \\
(X Y) &= \overline{X} + \overline{Y} & (X + Y) &= \overline{X} \overline{Y}
\end{align*}
\]

Boolean Algebraic Simplification Example

\[ y = ab + a + c \]
Boolean Algebraic Simplification Example

\[ y = ab + a + c \]

\[ = a(b + 1) + c \quad \text{distribution, identity} \]

\[ = a(1) + c \quad \text{law of 1's} \]

\[ = a + c \quad \text{identity} \]
Simplify \( Z = A + BC + \overline{A}(\overline{B}C) \)

- **A:** \( Z = 0 \)
- **B:** \( Z = A(1 + BC) \)
- **C:** \( Z = (A + BC) \)
- **D:** \( Z = BC \)
- **E:** \( Z = 1 \)
Signals and Waveforms: Showing Time & Grouping
Signals and Waveforms: Circuit Delay

\[ A = [a_3, a_2, a_1, a_0] \]
\[ B = [b_3, b_2, b_1, b_0] \]

\[ A \rightarrow \text{adder} \rightarrow C \]

\[ A \rightarrow \text{adder propagation delay} \]
Sample Debugging Waveform
Type of Circuits

- **Synchronous Digital Systems** consist of two basic types of circuits:
  - Combinational Logic (CL) circuits
    - Output is a function of the inputs only, not the history of its execution
    - E.g., circuits to add A, B (ALUs)
  - Sequential Logic (SL)
    - Circuits that “remember” or store information
    - aka “State Elements”
    - E.g., memories and registers (Registers)
Uses for State Elements

- Place to store values for later re-use:
  - Register files (like x1-x31 in RISC-V)
  - Memory (caches and main memory)
- Help control flow of information between combinational logic blocks
  - State elements hold up the movement of information at input to combinational logic blocks to allow for orderly passage
Accumulator Example

Why do we need to control the flow of information?

Want: \[ S = 0; \]

\[ \text{for } (i=0; i<n; i++) \]

\[ S = S + X_i \]

Assume:
- Each X value is applied in succession, one per cycle
- After n cycles the sum is present on S
First Try: Does this work?

No!
Reason #1: How to control the next iteration of the ‘for’ loop?
Reason #2: How do we say: ‘S=0’?
Register Internals

• n instances of a “Flip-Flop”
• Flip-flop name because the output flips and flops between 0 and 1
• D is “data input”, Q is “data output”
• Also called “D-type Flip-Flop”
Flip-Flop Operation

• Edge-triggered d-type flip-flop
  • This one is “positive edge-triggered”

• “On the rising edge of the clock, the input d is sampled and transferred to the output. At all other times, the input d is ignored.”

• Example waveforms:
Flip-Flop Timing

- Edge-triggered d-type flip-flop
  - This one is “positive edge-triggered”

- “On the rising edge of the clock, the input d is sampled and transferred to the output. At all other times, the input d is ignored.”

- Example waveforms (more detail):

  ![Example waveforms diagram](image-url)
Camera Analogy Timing Terms

• Want to take a portrait – timing right before and after taking picture
• *Set up time* – don’t move since about to take picture (open camera shutter)
• *Hold time* – need to hold still after shutter opens until camera shutter closes
• *Time click to data* – time from open shutter until can see image on output (viewscreen)
Hardware Timing Terms

• **Setup Time**: when the input must be stable *before* the edge of the CLK

• **Hold Time**: when the input must be stable *after* the edge of the CLK

• “CLK-to-Q” Delay: how long it takes the output to change, measured from the edge of the CLK
Accumulator Timing 1/2

- Reset input to register is used to force it to all zeros (takes priority over D input).
- $S_{i-1}$ holds the result of the $i^{th}$ iteration.
- Analyze circuit timing starting at the output of the register.
Accumulator Timing 2/2

- reset signal shown.
- Also, in practice X might not arrive to the adder at the same time as \( S_{i-1} \)
- \( S_i \) temporarily is wrong, but register always captures correct value.
- In good circuits, instability never happens around rising edge of clk.
Model for Synchronous Systems

- Collection of Combinational Logic blocks separated by registers
- Feedback is optional
- Clock signal(s) connects only to clock input of registers
- Clock (CLK): steady square wave that synchronizes the system
- Register: several bits of state that samples on rising edge of CLK (positive edge-triggered) or falling edge (negative edge-triggered)
Maximum Clock Frequency

- What is the maximum frequency of this circuit?

Hint:
Frequency = \( \frac{1}{\text{Period}} \)

Period = Max Delay = \( \text{CLK-to-Q Delay} + \text{CL Delay} + \text{Setup Time} \)
Critical Paths

Timing...

Note: delay of 1 clock cycle from input to output.
Clock period limited by propagation delay of adder/shifter.
Pipelining to improve performance

- Insertion of register allows higher clock frequency
- More outputs per second (higher bandwidth)
- But each individual result takes longer (greater latency)
Recap of Timing Terms

- **Clock (CLK)** - steady square wave that synchronizes system
- **Setup Time** - when the input must be stable before the rising edge of the CLK
- **Hold Time** - when the input must be stable after the rising edge of the CLK
- **“CLK-to-Q” Delay** - how long it takes the output to change, measured from the rising edge of the CLK
- **Flip-flop** - one bit of state that samples every rising edge of the CLK (positive edge-triggered)
- **Register** - several bits of state that samples on rising edge of CLK or on LOAD (positive edge-triggered)
What is maximum clock frequency? (assume all unconnected inputs come from some register)

- A: 5 GHz
- B: 200 MHz
- C: 500 MHz
- D: 1/7 GHz
- E: 1/6 GHz

Clock->Q  1ns
Setup 1ns
Hold 1ns
AND delay 1ns
