

1 RISC-V Instruction Translation

1.1 In this question, translate the following RISC-V instructions into their binary and hexadecimal values.

a) `addi s1 x0 -24` = 0b_____1.1
= 0x_____1.1

b) `sh s1 4(t1)` = 0b_____1.1
= 0x_____1.1

1.2 In this question, translate the following hexadecimal values into RISC-V instructions.

a) `0xFE05 0CE3` = _____
1.2

b) `0x2345 54B7` = _____
1.2

1.3 Given the following RISC-V code and instruction addresses, translate the `jal` and `bne` instructions (you'll need your RISC-V reference sheet!) and determine the value of `R[ra]` during the execution of `loop`.

```

loop:
0x002CFF00:    add t1, t2, t0      0x00538333

0x002CFF04:    jal ra, foo           _____
                                           1.3

0x002CFF08:    bne t1, zero, loop    _____
                                           1.3
...

foo:
0x002CFF2C:    jr ra              R[ra] = _____
                                           1.3

```

2 RISC-V Addressing

We have several *addressing modes* to access memory (immediate not listed):

- a) Base displacement addressing adds an immediate to a register value to create a data memory address (used for `lw`, `lb`, `sw`, `sb`).
- b) PC-relative addressing uses the PC and adds the immediate value of the instruction to create an instruction address (used by branch and jump instructions).
- c) Register Addressing uses the value in a register as an instruction address. For instance, `jalr`, `jr`, and `ret`, where `jr` and `ret` are just pseudoinstructions that get converted to `jalr`.

2.1 What is the range of 32-bit instructions that can be reached from the current PC using a single branch instruction? Note that RISC-V branch instructions must support branching to 16-bit “compressed” instructions (enabled via an optional RISC-V extension).

2.2 What is the maximum range of 32-bit instructions that can be reached from the current PC using a jump instruction?

3 Two-Pass Assembly

Consider the following assembly code. Assume that `printf` exists in the C standard library and that `msg` exists at an unknown address in the `.data` section.

Address	Assembly
<code>.data</code>	<code>msg: .string "Hello World"</code>
<code>.text</code>	
<code>0x0C</code>	<code>add t0, x0, x0</code>
<code>0x10</code>	<code>addi t1, x0, 4</code>
<code>0x14</code>	<code>loop: beq t0, t1, end</code>
<code>0x18</code>	<code>addi a0, a0, 1</code>
<code>0x1C</code>	<code>la a0, msg # load address of `msg`</code>
<code>0x20</code>	<code>jal ra, printf</code>
<code>0x24</code>	<code>n: addi t0, t0, 1</code>
<code>0x28</code>	<code>j loop</code>
<code>0x2C</code>	<code>end: ret</code>

3.1 This code is output from the _____ (Compiler, Assembler, Linker, or Loader) and _____ (may / may not) contain pseudoinstructions.

3.2 Assume we are using a two-pass assembler. Fill out the symbol table after the first pass (top-to-bottom) of the assembler. Not all lines may be used. The order of entries in the table do not matter.

Symbol Table	
Label	Address

3.3 After the first pass of the assembler, which of the instructions do not have their addresses fully resolved?

- 3.4 After the second pass of the assembler but before the linker, which of the instructions do not have their addresses fully resolved?
